

Case - Software Engineer

Tempo

Tempo is a self-hosted time-tracking app. Every release, someone on the team spends half a day reading through commit messages and writing the release notes by hand. They'd like that half day back.

The assignment

Build an app that turns Tempo's commit history into the release notes for v2.1.

Who the notes are for

Tempo's customers. They read the notes on a public page to find out what changed in the version they're about to install, so they're written for people who use the product rather than the people who built it. Someone at Tempo approves them before they go out, and that person isn't going to read the commit history to do it.

What you get

`case-materials.zip` contains:

<code>commits.json</code>	Tempo's commit history, 2,455 commits — author, date, subject, body, change stats
<code>diffs/<sha>.diff</code>	the code change for each commit that has one. The message is what the author said; the diff is what happened
<code>commits-followup.json</code>	a second batch of commits — see requirement 4

What we expect

Notes that get published exactly as they come out of your app, in Dutch and English, covering v2.1. On top of that:

1. **Everything in the release notes are true.** If the release notes say Tempo gained, changed or fixed something, that's what happened in this release.
2. **Every entry has to be traceable.** For any line in the release notes, we need to be able to see which commit it came from and your app should catch an entry that can't be traced back to one.
3. **The same history produces the same notes.** Read them, walk away, come back, nothing has quietly reworded itself. And when new commits arrive, the entries that didn't change don't change.
4. `commits-followup.json` **lands after you've already produced the notes.** The published notes have to end up right for the complete history.
5. **It runs on a commit history you haven't seen.** We'll bring our own.

There's no prescribed format for the notes themselves, that's your call.

Practicalities

Effort	3–4 hours. This is deliberately more than fits in 3–4 hours — decide what matters and leave the rest. Tell us what you cut.
Stack	Python. Use OpenRouter for whichever model you want.
Deliver	A link to your GitHub repo, and a link to the app if you deployed it. If you didn't, a README that gets us running from a clean machine — assume we won't debug it.
AI tools	Allowed and encouraged, we use them daily. You'll walk us through the code afterwards, so submit what you can explain.

Good luck.
